Algorithms

1.1 Count inversions

Description: Count the number of inversions when transforming the vector l in the vector r, which is also equivalent to the minimum number of swaps required.

Usage: If no r vector is provided it considers r as the sorted vector, if there is no such way to turn l into r using swaps then -1 is returned

Time: $O(N \log N)$

```
#pragma once
#include "../Contest/template.cpp"
template <typename T>
ll countInversions(vector<T> l, vector<T> r = {}) {
    if (!len(r)) r = l, sort(all(r));
    int n = len(l);
    vi v(n), bit(n);
    vector<pair<T, int>> w;
    rep(i, 0, n) w.eb(r[i], i + 1);
    sort(all(w));
    rep(i, 0, n) {
        auto it = lower bound(all(w), make pair(l[i], 0));
        if (it == w.end() or it->first != \overline{\lfloor (i) \rfloor} return -1; // impossible
        v[i] = it -> second:
        it->second = -1;
    il ans = 0:
    rrep(i, n - 1, 0 - 1) {
        for (int j = v[i] - 1; j; j = j \& -j) ans += bit[j];
        for (int j = v[i]; j < n; j += j \& -j) bit[j]++;
    return ans;
```

Ternary search (integer)

Description: Given a unimodal function f defined between the integers l and r finds an xsuch that f(x) is maximum/minimum.

Usage: Just pass the range l, r of the function you are interested, the function that receives an integer and if you want the maximum value use the cmp = greater < ll>(), otherwise less<ll>().

Time: $O(\log r - l + 1)$

Memory: O(1)

```
#include "../Contest/template.cpp"
template <auto cmp = greater<ll>()>
ll ternary search(ll l, ll r, function<ll(ll)> f) {
   static const ll eps = 3:
   while (r - l >= eps) {
       ll m1 = l + (r - l) / 3;
        ll m2 = r - (r - l) / 3;
        if (cmp(f(m1), f(m2)))
            r = m2;
       else
```

```
l = m1:
rep(i, l, r + 1) if (cmp(f(i), f(l))) l = i;
return l;
```

1.3 Ternary search (real)

```
#include "../Contest/template.cpp"
template <auto cmp = greater<ld>()>
ld ternarySearch(ld l, ld r, function<ld(ld)> f, const ld eps = 1e-9) {
    while (r - l >= eps) {
        ld m1 = l + (r - l) / 3;
        ld m2 = r - (r - l) / 3;
        if (cmp(f(m1), f(m2)))
            r = m2:
        else
            l = m1:
    }
    return l;
```

Combinatorics

2.1 Process all partitions of a set

```
Description: generate every distinct group of a set that contains elements from 0 to N-1,
and pass it to the given function "process". If N is 4 the sets generated would be:
[\{\{0,1,2,3\}\}] \ [\{\{0,1,2\},\{3\}\}] \ [\{\{0,1,3\},\{2\}\}] \ [\{\{0,1\},\{2,3\}\}] \ [\{\{0,1\},\{2\},\{3\}\}] \ [\{\{0,2,3\},\{1\}\}]]
[\{\{0,2\},\{1,3\}\}] \ [\{\{0,2\},\{1\},\{3\}\}] \ [\{\{0,3\},\{1,2\}\}] \ [\{\{0\},\{1,2,3\}\}] \ [\{\{0\},\{1,2\},\{3\}\}]]
[\{\{0,3\},\{1\},\{2\}\}] \ [\{\{0\},\{1,3\},\{2\}\}] \ [\{\{0\},\{1\},\{2,3\}\}] \ [\{\{0\},\{1\},\{2\},\{3\}\}]]
Time: O(B(N)), Bell Number of N
Memory: O(N)
```

```
#include "../Contest/template.cpp"
void process all partitions of a set(
    const int N, const function<void(const vi2d &)> process) {
    vi2d groups;
    groups.reserve(N);
    function<void(int)> dfs = [&](int idx) {
        if (idx == N) {
            process(groups);
            return:
        rep(i, 0, len(groups)) {
            groups[i].eb(idx);
            dfs(idx + 1);
            groups[i].ppb();
        groups.pb({idx});
        dfs(idx + 1);
```

```
groups.ppb();
};
_dfs(0);
```

```

4.8 Bitree 2D

Description: Given a 2D array you can increment an arbitrary position, and also query the subsum of a subgrid

Time: Update and query in $O(logN^2)$

```
struct Bit2d {
    int n;
    vll2d bit;
    Bit2d(int ni) : n(ni), bit(n + 1, vll(n + 1)) {}
    Bit2d(int ni, vll2d &xs) : n(ni), bit(n + 1, vll(n + 1)) {
        for (int i = 1; i <= n; i++) {
            for (int j = 1; j \le n; j++) {
                update(i, j, xs[i][j]);
        }
    void update(int x, int y, ll val) {
        for (; x \le n; x += (x \& (-x)))  {
            for (int i = y; i \le n; i += (i \& (-i))) {
                bit[x][i] += val:
    ill sum(int x, int y) {
        ll ans = 0;
        for (int i = x; i; i = (i \& (-i))) {
            for (int j = y; j; j = (j \& (-j))) {
                ans += bit[i][i]:
            }
        return ans:
    ll query(int x1, int y1, int x2, int y2) {
        return sum(x2, y2) - sum(x2, y1 - 1) - sum(x1 - 1, y2) +
               sum(x1 - 1, y1 - 1);
};
```

4.9 Convex Hull Trick / Line Container

Description: Container where you can add lines of the form mx + b, and query the maximum value at point x.

Usage: $insert_line(m, b)$ inserts the line $m \cdot x + b$ in the container.

eval(x) find the highest value among all lines in the point x.

Time: Eval and insert in $O(\log N)$

```
const ll LLINF = 1e18;
const ll is_query = -LLINF;
struct Line {
    ll m, b;
    mutable function<const Line *()> succ;
    bool operator<(const Line &rhs) const {
        if (rhs.b != is_query) return m < rhs.m;
        const Line *s = succ();</pre>
```

```
if (!s) return 0;
        ll x = rhs.m;
        return b - s -> b < (s -> m - m) * x;
struct Cht : public multiset<Line> { // maintain
                                       // max m*x+b
    bool bad(iterator y) {
        auto z = next(y);
        if (y == begin()) {
            if (z == end()) return 0;
            return y->m == z->m \&\& y->b <= z->b;
        auto x = prev(v):
        if (z == end()) return v->m == x->m && v->b <= x->b:
        return (ld) (x->b-y->b) * (z->m-y->m) >=
               (ld)(y->b-z->b) * (y->m-x->m);
    void insert line(ll m.
                     ll b) { // min -> insert (-m,-b) -> -eval()
        auto y = insert({m, b});
        v->succ = [=] \{ return next(v) == end() ? 0 : \&*next(v); \};
        if (bad(y)) {
            erase(y);
            return;
        while (next(y) != end() && bad(next(y))) erase(next(y));
        while (y != begin() && bad(prev(y))) erase(prev(y));
    il eval(ll x) {
        auto l = *lower bound((Line){x, is query});
        return l.m * x + l.b:
};
4.10 DSU (with rollback)
Description: Performs every operation a regular DSU does, but you can roll back to a
specific time.
Usage: int t = uf.time(); ...; uf.rollback(t); T
Time: O(\log(N))
struct RollbackUF {
    vi e;
    vector<pii> st;
    RollbackUF(int n) : e(n, -1) {}
    int size(int x) { return -e[find(x)]; }
    int find(int x) { return e[x] < 0 ? x : find(e[x]); }
    int time() { return len(st); }
    void rollback(int t) {
```

for (int i = time(); i-- > t;) e[st[i].first] = st[i].second;

st.resize(t);

bool join(int a, int b) {

a = find(a), b = find(b);

if (a == b) return false:

```
if (e[a] > e[b]) swap(a, b);
    st.push_back({a, e[a]});
    st.push_back({b, e[b]});
    e[a] += e[b];
    e[b] = a;
    return true;
}
};
```

4.11 DSU / UFDS

Usage: You may discomment the commented parts to find online which nodes belong to each set, it makes the $union_set$ method cost $O(log^2)$ instead O(A)

```
struct DSU {
   vi ps, sz;
   // vector<unordered set<int>> sts;
   DSU(int N)
        : ps(N + 1),
          sz(N, 1) /*, sts(N) */
        iota(ps.begin(), ps.end(), 0);
        // for (int i = 0; i < N; i++)
        // sts[i].insert(i);
   int find set(int x) { return ps[x] == x ? x : ps[x] = find set(ps[x]);
   int size(int u) { return sz[find set(u)]; }
   bool same set(int x, int y) { return find set(x) == find set(y); }
   void union set(int x, int y) {
        if (same set(x, y)) return;
        int px = find set(x);
        int py = find set(y);
        if (sz[px] < sz[py]) swap(px, py);
        ps[py] = px;
        sz[px] += sz[py];
        // sts[px].merge(sts[py]);
};
```

4.12 Lichao Tree (dynamic)

Description: Lichao Tree that creates the nodes dynamically, allowing to query and update from range [MAXL, MAXR]

Úsage:

- query(x): find the highest point among all lines in the structure
- add(a,b): add a line of form y=ax+b in the structure
- addSegment(a,b,l,r): add a line segment of form y=ax+b which covers from range [l,r]

Time: $O(\log N)$

```
template <typename T = ll, T MAXL = 0, T MAXR = 1 '000' 000'001>
struct LiChaoTree {
    static const T inf = -numeric limits<T>::max() / 2;

            add(li, cur, l, r);
            return;
        T mid = midpoint(l, r);
        if (l != r) {
            addSegment(li, cur->left, l, mid, lseg, rseg);
            addSegment(li, cur->right, mid + 1, r, lseg, rseg);
    }
```

```
void addSegment(T a, T b, T l, T r) {
    addSegment({a, b}, root, MAXL, MAXR, l, r);
};
```

4.13 Merge sort tree

Description: Like a segment tree but each node stores the ordered subsegment it represents.

Usage:

```
• inrange(l,r,a,b): counts the number of positions i, l \leq i \leq r such that a \leq x_i \leq b. Time: Build O(N\log N^2), inrange O(\log N^2) Memory: O(n\log N)
```

```
template <class T>
struct MergeSortTree {
    int n:
    vector<vector<T>> st:
    MergeSortTree(vector<T> &xs) : n(len(xs)), st(n << 1) {</pre>
        rep(i, 0, n) st[i + n] = vector<T>(\{xs[i]\});
        rrep(i, n - 1, 0) {
            st[i].resize(len(st[i << 1]) + len(st[i << 1 | 1]));
            merge(all(st[i << 1]), all(st[i << 1 | 1]), st[i].begin());
    int count(int i, T a, T b) {
        return upper bound(all(st[i]), b) - lower bound(all(st[i]), a);
    int inrange(int l, int r, T a, T b) {
        int ans = 0:
        for (l += n, r += n + 1; l < r; l >>= 1, r >>= 1) {
            if (l & 1) ans += count(l++, a, b);
            if (r \& 1) ans += count(--r, a, b):
        return ans;
};
```

4.14 Mex with update

Description: This DS allows you to mantain an array of elments, insert, and remove, and query the MEX at any time.

Usage:

- Mex(mxsz): Initialize the DS, mxsz must be the maximum number of elements that the structure may have.
- add(x): just adds one copy of x.
- rmv(x): just remove a copy of x.
- operator(): returns the MEX.

Time:

- Mex(mxsz): $O(\log mxsz)$
- add(x): $O(\log mxsz)$
- rmv(x): $O(\log mxsz)$

```
• operator(): O(1)
```

```
struct Mex {
    int mx sz;
    vi hs:
    set<int> st;
    Mex(int mx sz) : mx sz(mx sz), hs(mx sz + 1) {
        auto it = st.begin();
        rep(i, 0, mx sz + 1) it = st.insert(it, i);
    void add(int x) {
        if (x > mx sz) return;
        if (!hs[x]++) st.erase(x);
    void rmv(int x) {
        if (x > mx sz) return;
        if (!--hs[x]) st.emplace(x);
    int operator()() const { return *st.begin(); }
      Optional, you can just create with size
      len(xs) add N elements :D
    Mex(const vi &xs, int mx sz = -1) : Mex(\sim mx sz ? mx sz : len(xs)) {
        for (auto xi : xs) add(xi);
};
```

4.15 Orderd Set (GNU PBDS)

Usage: If you need an ordered **multi** set you may add an id to each value. Using greater equal, or less equal is considered undefined behavior.

- order_of_key (k): Number of items strictly smaller/greater than k .
- find by order(k): K-th element in a set (counting from zero).

Time: Both $O(\log N)$

Warning: Is 2 or 3 times slower then a regular set/map.

```
#include <ext/pb_ds/assoc_container.hpp>
#include <ext/pb_ds/tree_policy.hpp>
using namespace __gnu_pbds;
template <typename T>
using ordered_set =
    tree<T, null_type, less<T>, rb_tree_tag,
    tree_order_statistics_node_update>;
```

4.16 Prefix Sum 2D

Description: Given an 2D array with N lines and M columns, find the sum of the subarray that have the left upper corner at (x1, y1) and right bottom corner at (x2, y2).

Time: Build $O(N \cdot M)$, Query O(1).

4.17 Segment Tree Update Range Query (bottom-up)

```
* @Description:
        merge should be function<T(T,T)>, that
        makes the necessary operation between two
        nodes in the seament tree
* */
#include "../../Contest/template.cpp"
template <typename T, T identity, auto merge>
struct SegTreeBottomUp {
   int size;
   vector<T> arr;
   SegTreeBottomUp(int n) {
        for (size = 1; size < n; size <<= 1);</pre>
        arr.resize(size << 1);</pre>
   void assign(int pos, const T &val) {
        for (arr[pos += size] = val; pos >>= 1;)
            arr[pos] = merge(arr[pos << 1], arr[pos << 1 | 1]);</pre>
   T query(int l, int r) {
       T ans l = identity, ans r = identity;
        for (\bar{l} += size, r += size + 1; l < r; l >>= 1, r >>= 1) {
            if (l \& 1) ans l = merge(ans l, arr[l++]);
            if (r \& 1) ans r = merge(arr[--r], ans r);
        return merge(ans l, ans r);
   SegTreeBottomUp(const vector<T> &vec) : SegTreeBottomUp(len(vec)) {
        copy(all(vec), begin(arr) + size);
        rrep(i, size - 1, 0) arr[i] = merge(arr[i << 1], arr[i << 1 | 1]);
   }
```

```
};
using SegTreeBottomUpSumQuery =
    SegTreeBottomUp<ll, Oll, [](ll a, ll b) { return a + b; }>;
```

4.18 Sparse table

```
template <typename T = ll,
          auto cmp = [](T \& src1, T \& src2, T \& dst) \{ dst = min(src1, src2); \}
class SparseTable {
   private:
    int sz;
    vi loas:
    vector<vector<T>> st;
   public:
    SparseTable(const vector<T> \&v) : sz(len(v)), logs(sz + 1) {
        rep(i, 2, sz + 1) logs[i] = logs[i >> 1] + 1;
        st.resize(logs[sz] + 1, vector<T>(sz));
        rep(i, 0, sz) st[0][i] = v[i];
        for (int k = 1; (1 << k) <= sz; k++) {
            for (int i = 0; i + (1 << k) <= sz; i++) {
                cmp(st[k-1][i], st[k-1][i+(1 << (k-1))], st[k][i])
        }
    T query(int l, int r) {
        const int k = logs[r - l];
        cmp(st[k][l], st[k][r - (1 << k)], ret);
        return ret;
};
```

4.19 Static range queries

```
};
```

4.20 Venice Set

Description: A container that you can insert q copies of element e, increment every element in the container in x, query which is the best element and it's quantity and also remove k copies of the greatest element.

Time:

- add elment $O(\log N)$ • remove $O(\log N)$
- update: O(1)
- query O(1)

```
template <typename T = ll>
struct VeniceSet {
    using T2 = pair<T, ll>;
    priority queue<T2, vector<T2>, greater<T2>> pq;
   T acc;
    VeniceSet() : acc() {}
    void add element(const T &e, const ll q) { pq.emplace(e - acc, q); }
    void update all(const T &x) { acc += x; }
    T2 best() {
        auto ret = pq.top();
        ret.first += acc:
        return ret;
    void pop() { pq.pop(); }
    void pop k(int k) {
        auto [e, q] = pq.top();
        pq.pop();
        q -= k;
        if (q) pq.emplace(e, q);
};
```

4.21 Venice Set (complete)

Description: A container which you can insert elements update all at once and also make a few queries

Usage:

- $add_element(e, q)$: adds q copies of e, if no q is provided adds a single one
- $update_all(x)$: increment every value by x
- erase(e): removes every copy of e, and returns how much was removed.
- count(e): returns the number of e in the container
- high()/low(): returns the hightest/lowest element, and it's quantity
- $pop_low(q)/pop_high(q)$: removes q copies of the lowest/highest elements if no q is provided removes all copies of the lowest/highest element.

You may answer which is the K-th value and it's quantity using an ordered_set.

Probably works with other operations

Time: Considering N the number of distinct numbers in the container

- add_element(e, q): O(log (N))
 update_all(x):O(1)
 erase(e): O(log (N))
 count(e): O(log (N))
- high()/low(): O(1)
- $pop_low(q)/pop_high(q)$: worst case is $O(N \cdot \log{(N)})$ if you remove all elements and so on...

Warning: There is no error handling if you try to *pop* more elements than exists or related stuff

```
struct VeniceSet {
    set<pll> st:
    ll acc:
    VeniceSet() : acc() {}
    ll add element(ll e, ll q = 1) {
        q = erase(e);
        ė −= acc;
        st.emplace(e, q);
        return a:
    }
    void update all(ll x) { acc += x; }
    ll erase(ll e) {
        e -= acc;
        auto it = st.lb({e, LLONG MIN});
        if (it == end(st) || (*it).first != e) return 0;
        ll ret = (*it).second:
        st.erase(it):
        return ret;
    ll count(ll x) {
        x \rightarrow acc:
        auto it = st.lb({x, LLONG MIN});
        if (it == end(st) | (*it) \cdot first != x) return 0;
        return (*it).second:
    pll high() { return *rbegin(st); }
    pll low() { return *begin(st); }
    void pop high(ll q = -1) {
        if (q == -1) q = high().second;
        while (a) {
            auto [e, eq] = high();
            st.erase(prev(end(st)));
            if (eq > q) add element(e, eq - q);
            q = max(0ll, q - eq);
    void pop low(ll q = -1) {
        if (q == -1) q = low().second;
        while (a) {
            auto [e, eq] = low();
            st.erase(st.begin());
            if (eq > q) add element(e, eq - q);
            a = max(0ll, a - ea):
```

```
};
```

4.22 Wavelet tree

```

    }
};
```

5 Dynamic Programming

5.1 Binary Knapsack (bottom up)

Description: Given the points each element have, and it repespective cost, computes the maximum points we can get if we can ignore/choose an element, in such way that the sum of costs don't exceed the maximum cost allowed.

Time: O(N*W)

Warning: The vectors VS and WS starts at one, so it need an empty value at index 0.

```
const int MAXN(1'000), MAXCOST(1'000 * 20);
ll\ dp[MAXN + 1][MAXCOST + 1];
bool ps[MAXN + 1][MAXCOST + 1];
pair<ll, vi> knapsack(const vll &points, const vi &costs, int maxCost) {
   int n = len(points) - 1; // ELEMENTS START AT INDEX 1 !
    for (int m = 0; m <= maxCost; m++) {</pre>
        dp[0][m] = 0;
   for (int i = 1; i <= n; i++) {
        dp[i][0] = dp[i - 1][0] + (costs[i] == 0) * points[i];
        ps[i][0] = costs[i] == 0;
   for (int i = 1; i <= n; i++) {
        for (int m = 1; m <= maxCost; m++) {</pre>
            dp[i][m] = dp[i - 1][m], ps[i][m] = 0;
            int w = costs[i];
            ll v = points[i];
            if (w \le m \text{ and } dp[i-1][m-w] + v > dp[i][m]) {
                dp[i][m] = dp[i - 1][m - w] + v, ps[i][m] = 1;
        }
   }
   vi is:
   for (int i = n, m = maxCost; i >= 1; --i) {
        if (ps[i][m]) {
            is.emplace_back(i);
            m -= costs[i];
    return {dp[n][maxCost], is};
```

5.2 Edit Distance

Time: O(N * M)

```
int edit_distance(const string &a, const string &b) {
   int n = a.size();
   int m = b.size();
   vector<vi> dp(n + 1, vi(m + 1, 0));
   int ADD = 1, DEL = 1, CHG = 1;
   for (int i = 0; i <= n; ++i) {
        dp[i][0] = i * DEL;
   }
   for (int i = 1; i <= m; ++i) {
        dp[0][i] = ADD * i;
   }
   for (int i = 1; i <= n; ++i) {
        int add = dp[i][j - 1] + ADD;
        int del = dp[i - 1][j] + DEL;
        int chg = dp[i - 1][j - 1] + (a[i - 1] == b[j - 1] ? 0 : 1) *
    CHG;</pre>
```

```
dp[i][j] = min({add, del, chg});
}
return dp[n][m];
}
```

5.3 Knapsack

Description: Finds the maximum score you can achieve, given that you have N items, each item has a cost, a point and a quantity, you can spent at most maxcost and buy each item the maximum quantity it has.

Time: $O(n \cdot maxcost \cdot \log maxqtd)$

Memory: O(maxcost).

```
ll knapsack(const vi &weight, const vll &value, const vi &qtd, int maxCost
   ) {
    vi costs;
    vll values:
    for (int i = 0; i < len(weight); i++) {
        ll q = qtd[i];
        for (ll x = 1; x <= q; q -= x, x <<= 1) {
            costs.eb(x * weight[i]);
            values.eb(x * value[i]);
        if (q) {
            costs.eb(q * weight[i]);
            values.eb(q * value[i]);
    vll dp(maxCost + 1);
    for (int i = 0; i < len(values); i++) {</pre>

            if (i \ge costs[i]) dp[i] = max(dp[i], values[i] + dp[i - costs])
    [i]]);
    return dp[maxCost];
```

5.4 Longest Increasing Subsequence

Description: Find the pair (sz, psx) where sz is the size of the longest subsequence and psx is a vector where psx_i tells the size of the longest increase subsequence that ends at position i. $get_i dx$ just tells which indices could be in the longest increasing subsequence.

Time: $O(n \log n)$

```
template <typename T>
pair<int, vi> lis(const vector<T> &xs, int n) {
    vector<T> dp(n + 1, numeric_limits<T>::max());
    dp[0] = numeric_limits<T>::min();
    int sz = 0;
    vi psx(n);
    rep(i, 0, n) {
```

```
int pos = lower bound(all(dp), xs[i]) - dp.begin();
        sz = max(sz, pos);
        dp[pos] = xs[i];
        psx[i] = pos;
    return {sz, psx};
template <tvpename T>
vi get idx(vector<T> xs) {
   int n = xs.size();
   auto [sz1, psx1] = lis(xs, n);
   transform(rall(xs), xs.begin(), [](T x) { return -x; });
   auto [sz2, psx2] = lis(xs, n);
   vi ans;
   rep(i, 0, n) {
        int l = psx1[i];
        int r = psx2[n - i - 1];
        if (l + r - 1 == sz1) ans.eb(i);
    return ans;
```

5.5 Monery sum

Description: Find every possible sum using the given values only once.

```
set<int> money sum(const vi &xs) {
    using vc = vector<char>;
    using vvc = vector<vc>;
    int m = accumulate(all(xs), 0);
    int n = xs.size();
    vvc = dp(n + 1, vc(m + 1, 0));
    set<int> ans;
    dp[0][xs[0]] = 1;
    for (int i = 1; i < _n; ++i) {
        for (int j = 0; \bar{j} \le m; ++j) {
            if (i == 0 \text{ or } dp[i - 1][i]) {
                 dp[i][j + xs[i]] = 1;
                _{dp[i][j] = 1;}
        }
    for (int i = 0; i < _n; ++i)
        for (int j = 0; j \le m; ++j)
            if (_dp[i][j]) _ans.insert(j);
    return _ans;
}
```

5.6 Steiner tree

```
template <typename T>
T steinerCost(const vector<vector<T>> &adj, const vi ks,
              T inf = numeric limits<T>::max()) {
    int k = len(ks), n = len(adj);
    vector<vector<T>> dp(n, vector<T>(1 << k, inf));</pre>
    vi inks(n);
    trav(ki, ks) inks[ki] = 1;
    trav(ki, ks) {
        rep(j, 0, n) {
            if (count(all(ks), j) == 0) {
                dp[i][1 << ki] = adi[ki][i];</pre>
        }
    rep(mask, 2, (1 << k)) {
        rep(i, 0, n) {
            if (inks[i]) continue;
            for (int mask2 = (mask - 1) & mask; mask2 >= 1;
                 mask2 = (mask2 - 1) \& mask) 
                int mask3 = mask ^ mask2;
                chmin(dp[i][mask], dp[i][mask2] + dp[i][mask3]);
            rep(j, 0, n) {
                if (inks[j]) continue;
                chmin(dp[j][mask], dp[i][mask] + adj[i][j]);
        }
    T ans = inf:
    rep(i, 0, n) chmin(ans, dp[i][(1 << k) - 1]);
    return ans;
```

5.7 Sum of Subsets

Description: Allows you to find if some mask X is a super mask of any of the given masks **Usage**: Call *build* with the *masks* then it returns a vector of bool V where V_X says if X is a super mask of any of the initial maks

You can change it to count how many submasks of each mask exsists, by changing the bitwise or by a plus sign...

Time: $O(LOG \cdot 2^{LOG})$ Memory: $O(LOG^2 \cdot 2^{LOG})$

Warning: Remember to set LOG with the highest bit possible

```
const int LOG = 20;
vc build(const vi &masks) {
   vc ret(1 << LOG);
   trav(mi, masks) ret[mi] = 1;
   rep(b, 0, LOG) {
        rep(mask, 0, (1 << LOG)) {
            if (mask & (1 << b)) ret[mask] |= ret[mask ^ (1 << b)];
        }
    }
   return ret;
}</pre>
```

5.8 Travelling Salesman Problem

```
Time: O(N^2 \cdot 2^N)

Memory: O(N^2 \cdot 2^N)

vll2d dist;

vll memo;

int tsp(int i, int mask, int N) {

   if (mask == (1 << N) - 1) return dist[i][0];

   if (memo[i][mask] != -1) return memo[i][mask];

   int ans = INT_MAX << 1;

   for (int j = \overline{0}; j < N; ++j) {

      if (mask & (1 << j)) continue;

      auto t = tsp(j, mask | (1 << j), N) + dist[i][j];

      ans = min(ans, t);
   }

   return memo[i][mask] = ans;
}
```

6 Extras

6.1 Binary to gray

```
string binToGray(string bin) {
    string gray(bin.size(), '0');
    int n = bin.size() - 1;
    gray[0] = bin[0];
    for (int i = 1; i <= n; i++) {
        gray[i] = '0' + (bin[i - 1] == '1') ^ (bin[i] == '1');
    }
    return gray;
}</pre>
```

6.2 Get permutation cycles

Description: Receives a permutation [0, n-1] and return a vector 2D with each cycle.

```
vll2d getPermutationCicles(const vll &ps) {
    ll n = len(ps);
    vector<char> visited(n);
    vector<vll> cicles;
    rep(i, 0, n) {
        if (visited[i]) continue;
        vll cicle;
        ll pos = i;
        while (!visited[pos]) {
            cicle.pb(pos);
            visited[pos] = true;
            pos = ps[pos];
        }
        cicles.push_back(vll(all(cicle)));
    }
    return cicles;
}
```

6.3 Max & Min Check

Description: Returns the min/max value in range [l, r] that satisfies the lambda function check, if there is no such value the 'nullopt' is returned.

Usage: check must be a function that receives an integer and return a boolean.

Time: $O(\log r - l + 1)$

```
template <typename T>
optional<T> maxCheck(T l, T r, auto check) {
    optional<T> ret;
    while (l <= r) {
        T m = midpoint(l, r);
        if (check(m))
            ret ? chmax(ret, m) : ret = m, l = m + 1;
        else
            r = m - 1:
    return ret:
template <typename T>

    optional<T> ret;
    while (l <= r) {
        T m = midpoint(l, r);
        if (check(m))
            ret ? chmin(ret, m) : ret = m, r = m - 1;
        else
            l = m + 1:
    return ret:
```

6.4 Merge Interals

Time: $(N \log N)$

Warning: It destroys the original array

```
#include "../Contest/template.cpp"
template <typename T>
vector<pair<T, T>> merge_intervals(vector<pair<T, T>> &intervals) {
   if (!len(intervals)) return {};
   using Pt = pair<T, T>;
   sort(all(intervals));
   vector<Pt> ret{intervals.front()};
   rep(i, 1, len(ret)) {
      auto &[pl, pr] = ret.back();
      auto &[l, r] = intervals[i];
      if (l <= pr)
            chmax(pr, r);
      else
            ret.eb(l, r);</pre>
```

```
return ret:
6.5 Mo's algorithm

8.2 2-SAT

};

Description: Calculates a valid assignment to boolean variables a, b, c,... to a 2-SAT problem, so that an expression of the type (a||b)&&(!a||c)&&(d||!b)&&... becomes true, or reports that it is unsatisfiable.

Usage: Negated variables are represented by bit-inversions (x).

Returns true iff it is solvable ts.values[0..N-1] holds the assigned values to the vars.

Time: O(N+E), where N is the number of boolean variables, and E is the number of clauses.

```
struct TwoSat {
   int N;
   vector<vi> gr;
   vi values: // 0 = false, 1 = true

```

8.6 Biconnected Components

Description: Build a vector of vectors, where the i-th vector correspond to the nodes of the i-th, biconnected component, a biconnected component is a subset of nodes and edges in which there is no cut point, also exist at least two distinct routes in vertex between any two vertex in the same biconnected component.

Time: O(N+M)

```
const int maxn(5 '00' 000);
int tin[maxn], stck[maxn], bcc cnt, n, top = 0, timer = 1;
vector<int> g[maxn], nodes[maxn];
int tarjan(int u, int p = -1) {
    int lowu = tin[u] = timer++;
    int son cnt = 0;
    stck[++\overline{top}] = u;
    for (auto v : g[u]) {
        if (!tin[v]) {
            son cnt++;
            int lowx = tarjan(v, u);
            lowu = min(lowu, lowx);
            if (lowx >= tin[u]) {
                 while (top != -1 \& \& stck[top + 1] != v)
                     nodes[bcc cnt].emplace back(stck[top--]);
                 nodes[bcc cnt++].emplace back(u);
        } else {
            lowu = min(lowu, tin[v]);
    if (p == -1 \&\& son_cnt == 0) {
```

```
nodes[bcc_cnt++].emplace_back(u);
}
return lowu;
}
void build_bccs() {
    timer = 1;
    top = -1;
    memset(tin, 0, sizeof(int) * n);
    for (int i = 0; i < n; i++) nodes[i] = {};
    bcc_cnt = 0;
    for (int u = 0; u < n; u++)
        if (!tin[u]) tarjan(u);
}</pre>
```

8.7 Binary Lifting/Jumping

Description: Given a function/successor grpah answers queries of the form which is the node after k moves starting from u.

Time: Build $O(N \cdot MAXLOG2)$, Query O(MAXLOG2).

```
const int MAXN(2e5), MAXLOG2(30);
int bl[MAXN][MAXLOG2 + 1];
int N;
int jump(int u, ll k) {
    for (int i = 0; i <= MAXLOG2; i++) {
        if (k & (1ll << i)) u = bl[u][i];
    }
    return u;
}
void build() {
    for (int i = 1; i <= MAXLOG2; i++) {
        for (int j = 0; j < N; j++) {
            bl[j][i] = bl[bl[j][i - 1]][i - 1];
        }
    }
}</pre>
```

8.8 Bipartite Graph

Description: Given a graph, find the 'left' and 'right' side if is a bipartite graph, if is not then a empty vi2d is returned

Time: O(N+M)

```
vi2d bipartite_graph(vi2d &adj) {
    int n = len(adj);
    vi side(n, -1);
    vi2d ret(2);
    rep(u, 0, n) {
        if (side[u] == -1) {
            queue<int> q;
            q.emp(u);
            side[u] = 0;
            ret[0].eb(u);
        }
}
```

```
while (len(q)) {
    int u = q.front();
    q.pop();
    for (auto v : adj[u]) {
        if (side[v] == -1) {
            side[v] = side[u] ^ 1;
            ret[side[v]].eb(v);
            q.push(v);
        } else if (side[u] == side[v])
            return {};
    }
    }
}
return ret;
}
```

8.9 Block-Cut tree

```
struct block cut tree {
    int n:
    vector<int> id, is cutpoint, tin, low, stk;
    vector<vector<int>> comps, tree;
    block cut tree(vector<vector<int>> &g)
        : n(g.size()), id(n), is cutpoint(n), tin(n), low(n) {
        // build comps
        for (int i = 0; i < n; i++) {
            if (!tin[i]) {
                int timer = 0;
                dfs(i, -1, timer, g);
        }

        return r;
};
```

8.12 D'Escopo-Pape

Description: Is a single source shortest path that works faster than Dijkstra's algorithm and the Bellman-Ford algorithm in most cases, and will also work for negative edges. However not for negative cycles. There exists cases where it runs in exponential time. **Usage:** Returns a pair containing two vectors, the first one with the distance from s to every other node, and another one with the ancestor of each node, note that the ancestor of s is -1

```
using Edge = pair<ll, int>;
using Adj = vector<vector<Edge>>;
pair<vll, vi> desopo_pape(int s, int n, const Adj &adj) {
    vll ds(n, LLONG_MAX), ps(n, -1);
    ds[s] = 0;
    vi ms(n, 2);
    deque<int> q;
    q.eb(s);
    while (len(q)) {
        int u = q.front();
        q.pop_front();
        ms[u] = 0;
        for (auto [w, v] : adj[u]) {
```

```
if (chmin(ds[v], w + ds[u])) {
    ps[v] = u;
    if (ms[v] == 2)
        ms[v] = 1, q.pb(v);
    else if (ms[v] == 0)
        ms[v] = 1, q.pf(v);
}

return {ds, ps};
```

8.13 Dijkstra

```
const int MAXN = 1'00'000;
const ll MAXW = 1'000'00011;
constexpr ll 00 = MAXW * MAXN + 1;
using Edge = pair<ll, int>; // { weigth, node}

   )]; }
};
```

8.26 Lowest Common Ancestor (Binary Lifting)

Description: Given a directed tree, finds the LCA between two nodes using binary lifting, and answer a few queries with it.

Usage:

- lca: returns the LCA between the two given nodes
- on path: fids if c is in the path from a to b

Time: build $O(N \cdot MAXLOG_2)$, all queries $O(MAXLOG_2)$

```
struct LCA {
   int n;
   const int maxlog;
```

```
vector<vector<int>> up:
vector<int> depth:
LCA(const vector<vector<int>> &tree)
    : n(tree.size()).
      maxlog(ceil(log2(n))),
      up(n, vector<int>(maxlog + 1)),
      depth(n, -1) {
    for (int i = 0; i < n; i++) {
        if (depth[i] == -1) {
            depth[i] = 0;
            dfs(i, -1, tree);
    }
void dfs(int u, int p, const vector<vector<int>> &tree) {
    if (p != -1) {
        depth[u] = depth[p] + 1;
        up[u][0] = p;
        for (int i = 1; i <= maxlog; i++) {
            up[u][i] = up[up[u][i - 1]][i - 1];
    for (int v : tree[u]) {
        if (v == p) continue;
        dfs(v, u, tree);
}
int kth jump(int u, int k) {
    for (int i = maxlog; i \ge 0; i--) {
        if ((1 << i) & k) {
            u = up[u][i];
    return u;
int lca(int u, int v) {
    if (depth[u] < depth[v]) swap(u, v);</pre>
    int diff = depth[u] - depth[v];
    u = kth jump(u, diff);
    if (u == v) return u;
    for (int i = maxlog; i \ge 0; i--) {
        if (up[u][i] != up[v][i]) {
            u = up[u][i];
            v = up[v][i];
    return up[u][0];
bool on path(int u, int v, int s) {
    int uv = lca(u, v), us = lca(u, s), vs = lca(v, s);
    return (uv == s or (us == uv and vs == s) or (vs == uv and us == s
));
int dist(int u, int v) {
```

```
return depth[u] + depth[v] - 2 * depth[lca(u, v)];
};
```

8.27 Maximum flow (Dinic)

Description: Finds the **maximum flow** in a graph network, given the **source** s and the **sink** t. Add edge from a to b with capcity c.

Time: In general $O(E \cdot V^2)$, if every capacity is 1, and every vertice has in degree equal 1 or out degree equal 1 then $O(E \cdot \sqrt{V})$,

Warning: Suffle the edges list for every vertice may take you out of the worst case

```
struct Dinic {
   struct Edge {
        int to, rev;
        ll c, oc;
       ll flow() { return max(oc - c, OLL); } // if you need flows
   };
   vi lvl, ptr, q;
   vector<vector<Edge>> adi;
   Dinic(int n) : lvl(n), ptr(n), q(n), adj(n) {}
   void addEdge(int a, int b, ll c, ll rcap = 0) {
       adj[a].pb({b, len(adj[b]), c, c});
       adj[b].pb({a, len(adj[a]) - 1, rcap, rcap});
   ll dfs(int v, int t, ll f) {
       if (v == t || !f) return f;
        for (int &i = ptr[v]; i < len(adj[v]); i++) {</pre>
            Edge &e = adi[v][i]:
            if (lvl[e.to] == lvl[v] + 1)
                if (ll p = dfs(e.to, t, min(f, e.c))) {
                    e.c -= p, adj[e.to][e.rev].c += p;
                    return p;
        return 0;
   ll maxFlow(int s, int t) {
       ll flow = 0:
       q[0] = s;
        rep(L, 0, 31) {
            do { // 'int L=30' maybe faster for random
                  // data
                lvl = ptr = vi(len(q));
                int qi = 0, qe = lvl[s] = 1;

                    for (Edge e : adj[v])
                        if (!lvl[e.to] && e.c >> (30 - L))
                            q[qe++] = e.to, lvl[e.to] = lvl[v] + 1;
                while (ll p = dfs(s, t, LLONG_MAX)) flow += p;
            } while (lvl[t]);
```

```
}
return flow;
}
bool leftOfMinCut(int a) { return lvl[a] != 0; }
};
```

8.28 Minimum Cost Flow

Description: Given a network find the minimum cost to achieve a flow of at most f. Works with **directed** and **undirected** graphs **Usage**:

- add(u, v, c, w): adds an edge from u to v with capacity c and cost w.
- flow(f): return a pair (flow, cost) with the maximum flow until f with source at s and sink at t, with the minimum cost possible.

Time: $O(N \cdot M + f \cdot m \log n)$

```
template <typename T>
struct MinCostFlow {
    struct Edge {
        int to:
        ll c, rc; // capcity, residual capacity
        T w:
                   // cost
    };

13.14 Suffix-Tree (Ukkonen's Algorithm)

```
#pragma once
#include <bits/stdc++.h>
using namespace std;
* Author: Unknown
* Date: 2017-05-15
* Source: https://e-maxx.ru/algo/ukkonen
 * Description: Ukkonen's algorithm for online suffix tree construction.
* Each node contains indices [l, r) into the string, and a list of child
 * nodes. Suffixes are given by traversals of this tree, joining [l, r)
 * substrings. The root is 0 (has l = -1, r = 0), non-existent children
 * To get a complete tree, append a dummy symbol -- otherwise it may
   an incomplete path (still useful for substring matching, though).
 * Time: $0(26N)$
* Status: stress-tested a bit
struct SuffixTree {
   enum { N = 200010, ALPHA = 26 }; // N \sim 2*maxlen+10
